Family Caregivers and Trauma

Who is a Family Caregiver?

A family caregiver is a family member, partner, or friend who provides a broad range of assistance to an older adult or adult with a chronic, disabling, or serious health condition. Family caregivers are not professionally employed to care for their loved one, may or may not have prior experience in caregiving, and can live with or separately from those they care for.

What does a Family Caregiver do?

Family caregivers provide their loved ones with a wide range of support from dressing and bathing, to emotional companionship, administering medication, or carrying out medical or nursing tasks. Additionally, family caregivers are often employed in the workforce and care for other dependents. Family caregivers:

- Help with daily activities including errands
- Provide emotional and social support
- Perform complex medical and nursing tasks
- Coordinating medical treatment and care

41 Million

Individuals in the United States are family caregivers, more than the population of California.

34 Billion

Hours of care are provided by family caregivers in the United States annually.

$470 Billion

Family caregivers provide annual care valued at $470 billion.

The economic value of Family Caregivers compares to the following sectors of annual spending in the United States:

- $366B Out-of-Pocket Health Care Spending
- $470B Family Caregiver Value
- $366B Overall Long-Term Care Spending
- $145B Medicaid Long-Term Care Spending
- $438B Agriculture, Forestry and Mining Sector
- $460B Education and Arts/Entertainment Sector

95% of older adults receive some help with daily activities from their family or close friends.

66% of older adults rely solely on family caregivers.

48% of older adults have difficulty carrying out daily living activities without assistance.

Family Caregiver Burden

While caregiving for a family member or friend can be a rewarding experience, it is also one that can take a financial, emotional, and physical toll. Family caregivers can experience:

- Increased emotional hardships on individual or family relationships
- Increased financial burden of providing care and/or forgoing paid work
- Increased exhaustion from the physical demands of caregiving
- Increased risk for chronic loneliness and social isolation
- Increased levels of stress and anxiety
- Increased levels of depression, which can persist after nursing home placement
- Decreased rate of self-care and health maintenance behaviors
- Worsening physical health

72% of caregivers report that they do not go to the doctor as often as they should.

63% of caregivers report worsening eating habits as a result of caregiving responsibilities.

58% of caregivers report worsening exercising habits as a result of caregiving responsibilities.

55% of caregivers missed doctor appointments.

45% of caregivers report chronic conditions at nearly twice the rate of non-caregivers.

11% of caregivers report that caregiving has caused their physical health to get worse.

#1 Declining health among family caregivers is the leading cause of the institutionalization of their loved ones.

Caregiving Can Be Rewarding

Many family caregivers find satisfaction in providing for their loved one’s care. Family caregivers report learning new skills, developing a new appreciation for life, feeling needed, and forming stronger relationship with their loved one.
Older Adults with Alzheimer’s and other Dementias

Individuals with dementia suffer from progressive cognitive deterioration resulting in changing behaviors and needs. Thus, providing care for older adults with Alzheimer’s and other dementias is very complex and challenging, placing additional stress and burden on family caregivers. 22

16 Million family caregivers in the United States provide care to those with Alzheimer’s and other dementias. 23

80% of older adults with Alzheimer’s and other dementias receive help with daily personal care activities (bathing, dressing, grooming, or eating), compared to 20% of adults without dementias who need similar support. 24

Employment Burden

Caring for older adults with Alzheimer’s and other dementias is a significant burden on the professional employment of family caregivers. As a result, more than 1 in 6 family caregivers of those with Alzheimer’s and other dementias have to quit working to become a caregiver or because caregiving duties become too burdensome. For family caregivers of those with Alzheimer’s and other dementias who remain at work, many have to adjust their work schedule to accommodate caregiving responsibilities. Some family caregivers report being penalized at work for taking time off to care for loved ones with Alzheimer’s or other dementias. 25

Health Burden

Providing care for individuals with dementia can be more stressful and physically demanding than caring for a physically impaired older adults. 30, 31 Of family caregivers of those with Alzheimer’s and dementias, many report worsening physical and mental health.

2X Family caregivers for individuals with Alzheimer’s and other dementias are twice as likely to suffer from depression than other family caregivers 32

6X Spousal caregivers for individuals with Alzheimer’s or other dementias are six times more likely to develop dementia compared to non-caregivers 33

Family Caregiver Mortality

The burden of caring for a person with dementia is significant and can affect a family caregiver’s mortality. 37 A study looking at spousal caregivers of hospitalized individuals found that if the hospitalized individual had dementia, the spousal caregiver was more likely to die within a year than if the care recipient did not have dementia, even after accounting for the age of the caregiver. 38

57% had to go in late, leave early, or take time off of work 26

18% had to reduce employment from full-time to part-time 27

16% had to take a leave of absence from their work 28

8% had to turn down a promotion at work 29

75% are somewhat or very concerned about maintaining their own health 34

60% experience high or very high emotional stress 35

33% report worsening health due to caregiving responsibilities 36

63% Family caregivers for individuals with Alzheimer’s or other dementias experience a 63% increased risk of death over four years compared to non-caregivers. 39
## Family Caregivers and Trauma

### Caregiving for Older Adults with a History of Trauma

Providing care for a family member or friend with a history of trauma can increase the complexity associated with their care.

### Caregiving of Veterans

Many wounded, injured, or disabled veterans rely on family caregivers for daily care and support. While this support is necessary for veterans to age in place, caregiving for older adults with a history of trauma can be challenging and comes with increased burdens. Family caregivers of military veterans consistently experience worse health than non-caregivers, report more workplace problems than other family caregivers, and are at increased risk for social isolation and depression than other caregivers.
